Sample Question and Model Answer Based on October November Biology 0610 Qn 2013

Sample Question:

Describe the process of DNA replication and explain its significance in cell division.

Model Answer:

DNA replication is a fundamental process that occurs during the S phase of the cell cycle, ensuring each daughter cell receives an identical copy of genetic material. The process begins with the unwinding of the double helix by the enzyme helicase, creating two single strands that serve as templates. DNA polymerase then adds complementary nucleotides to each template strand in a 5' to 3' direction, following base pairing rules (A with T, G with C). This results in the formation of two identical DNA molecules, each consisting of one original and one newly synthesized strand—a process termed semi-conservative replication.

The significance of DNA replication lies in its role in maintaining genetic continuity across cell divisions. Accurate replication ensures that genetic information is preserved, allowing for proper growth, development, and repair of organisms. Errors in replication can lead to mutations, which may have beneficial, neutral, or detrimental effects.
